### 9.2 Neyman-Pearson Paradigm

Let $\underline{X}=\left(X_{1}, \ldots, X_{n}\right)$ denote a sample from population $f(x \mid \theta)$.
Decide on $\mathrm{H}_{0}$ vs. $\mathrm{H}_{\mathrm{A}}$ based on the sample.
A decision on whether or not to reject
$\qquad$ $\mathrm{H}_{0}$ in favor of $\mathrm{H}_{\mathrm{A}}$ is made on the basis of a statistic

$$
T=T(\underline{X})=T\left(X_{1}, \ldots, X_{n}\right) .
$$

The set of values of T for which $\mathrm{H}_{0}$ is accepted is called the acceptance region and the set of values of T for which $\mathrm{H}_{0}$ is rejected is the rejection region of the test.

Two kinds of error may occur:

1. $\mathrm{H}_{0}$ is rejected when it is true: Type I error.
P (type I error) $=\alpha$ $=P\left(T \in\right.$ rejection region | $\mathrm{H}_{0}$ true $)$.

If $\mathrm{H}_{0}$ is simple, $\alpha$ is called the significance level of the test.

STAT 703//703 B.Habing Univ. of SC
will $\mathrm{h}^{4}$
${ }^{5}$
2. $\mathrm{H}_{0}$ is accepted when it is false: Type II error.
$P($ type II error $)=\beta$
$=P\left(T\right.$ in acceptance region $\mid \mathrm{H}_{0}$ false $)$
If $\mathrm{H}_{\mathrm{A}}$ is composite, $\beta$ depends on which member of $\mathrm{H}_{\mathrm{A}}$ is the true pdf.

| 2. $\mathrm{H}_{0}$ is accepted when it is false: <br> Type II error. <br> $\mathrm{P}($ type II error $)=\beta$ <br> $=\mathrm{P}\left(\mathrm{T}\right.$ in acceptance region \| $\mathrm{H}_{0}$ false $)$ <br> If $\mathrm{H}_{\mathrm{A}}$ is composite, $\beta$ depends on <br> which member of $\mathrm{H}_{\mathrm{A}}$ is the true <br> pdf. <br> star |

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

```
Power of the test =P(H
    when false)
    =1-P(H0}\mathrm{ is accepted | H}\mp@subsup{H}{0}{}\mathrm{ false )
    = 1- }\beta\mathrm{ .
```

Ideally, we would want $\alpha=\beta=0$, but
this not possible since the decision is based on data.

## Example:

Consider testing
$\mathrm{H}_{0}: \mathrm{p}=0.5$
vs. $H_{A}: p=0.6$
for a binomial sample of size $\mathrm{n}=10$.
$\qquad$
$P$-value The $p$-value is the probability of observing a test statistic at least as extreme as the one observed if the null hypothesis $\qquad$ is true.

The null hypothesis is rejected when $\qquad$ p -value is $\leq \alpha$. It is the smallest $\alpha$ for which $\mathrm{H}_{0}$ would be rejected. $\qquad$

STAT 703//703 B.Habing Univ. of SC $\qquad$

## Example 2:

## Consider testing

$H_{0}: p=0.5$
vs. $H_{A}: p>0.5$
for a binomial sample of size $\mathrm{n}=10$.

For a composite test the significance level $\alpha$ is the maximum (supremum) of the probabilities of a Type I error over all the possible alternatives.
