Contingency tables I

Timothy Hanson

Department of Statistics, University of South Carolina

Stat 506: Introduction to Experimental Design

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

Binary data

- So far we have considered designs that have led to *continuous* outcomes, e.g. hours until bond failure, number of salable flowers, etc.
- Many experimental designs lead to *discrete* outcomes, with the simplest being whether some event has occurred, e.g. cancer going into remission, cure of a rash, etc.
- Without loss of generality, we will consider binary outcomes of "success" and "failure".
- As with continuous data, the simplest design is to consider one factor with two levels; this is where we start.

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

Two-sample binary data

- Consider two populations and will want to compare two population proportions p_1 and p_2.
- In population 1, we observed y_1 out of n_1 successes; in population 2 we observed y_2 out of n_2 successes.
- This information can be placed in a contingency table

		Group	
		1	2
Outcome	Success	y_1	y_2
	Failure	$n_1 - y_1$	$n_2 - y_2$
	Total	n_1	n_2

- $\hat{p}_1 = y_1/n_1$ estimates p_1 & $\hat{p}_2 = y_2/n_2$ estimates p_2.

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

Migraine headache

- Migraine headache patients took part in a double-blind clinical trial to assess experimental surgery.
- 75 patients were randomly assigned to real surgery on migraine trigger sites ($n_1 = 49$) or sham surgery ($n_2 = 26$) in which an incision was made but nothing else.
- The surgeons hoped that patients would experience "a substantial reduction in migraine headaches," which we will label as success.

Introduction
2 × 2 contingency tables
Fishers exact test
r × k contingency table

Migraine headache

Response to migraine surgery			
		Surgery	
		Real	Sham
Substantial reduction	Success	41	15
in migraine headaches?	No success	8	11
	Total	49	26

- $\hat{p}_1 = 41/49 = 83.7\%$ for real surgeries.
- $\hat{p}_2 = 15/26 = 57.7\%$ for sham surgeries.
- Real appears to be better than sham, but is this difference significant?

Introduction
2 × 2 contingency tables
Fishers exact test
$r \times k$ contingency table

HIV testing

A random sample of 120 college students found that 9 of the 61 women in the sample had taken an HIV test, compared to 8 of the 59 men.

	HIV testing data	
	Female	Male
HIV test	9	8
No HIV test	52	51
Total	61	59

- $\hat{p}_1 = 9/61 = 14.8\%$ tested among women.
- $\hat{p}_2 = 8/59 = 13.6\%$ tested among men.
- These are pretty close.

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

Conditional probabilities

- p_1 and p_2 are *conditional probabilities*.
- For the migraine data, $p_1 = P\{\text{success}|\text{real}\}$ and $p_2 = P\{\text{success}|\text{sham}\}$. $\hat{p}_1 = 0.84$ and $\hat{p}_2 = 0.58$ estimate these conditional probabilities.
- For the HIV testing data, $p_1 = P\{\text{tested}|\text{female}\}$ and $p_2 = P\{\text{tested}|\text{male}\}$. $\hat{p}_1 = 0.15$ and $\hat{p}_2 = 0.14$ estimate these conditional probabilities.

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

χ^2 test for independence

- *No difference* between groups when $H_0 : p_1 = p_2$ is true.
- That is, $H_0 : P\{success|group\ 1\} = P\{success|group\ 2\}$.
- If H_0 is true then the outcome (migraine reduction, being tested for HIV, etc.) is *independent* of the group.
- This is tested using the chi-square statistic

$$\chi_S^2 = \sum_{i=1}^{4} \frac{(o_i - e_i)^2}{e_i},$$

  where $i = 1, 2, 3, 4$ are the four cells in the middle of the contingency table.
- The o_i are the observed counts and the e_i are what's expected if $p_1 = p_2$.

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

Computing e_i

- If $H_0 : p_1 = p_2$ is true then we can estimate the common probability $p = p_1 = p_2$ by $\hat{p} = (y_1 + y_2)/(n_1 + n_2)$. This is $\hat{p} = 56/75 = 0.747$ for migraine data.

- In the upper left corner we'd expect to see $\hat{p} n_1 = 0.747(49) = 36.59$ successes in the real surgery group, and so $49 - 36.59 = 12.41$ failures in the lower left.

- In the upper right corner we'd expect to see $\hat{p} n_2 = 0.747(26) = 19.41$ successes in the sham surgery group, and so $26 - 19.41 = 6.59$ failures in the lower right.

Introduction
2 × 2 contingency tables
Fishers exact test
r × k contingency table

Observed and expected under H_0

	Observed and expected frequencies for migraine study		
	Surgery		Total
	Real	Sham	
Success	41 (36.59)	15 (19.41)	56
No success	8 (12.41)	11 (6.59)	19
Total	49	26	75

$$\chi_S^2 = \frac{(41 - 36.59)^2}{36.59} + \frac{(15 - 19.41)^2}{19.41} + \frac{(8 - 12.41)^2}{12.41} + \frac{(11 - 6.59)^2}{6.59} = 6.06.$$

Introduction
2 × 2 contingency tables
Fishers exact test
r × k contingency table

The P-value

- When $H_0 : p_1 = p_2$ is true, χ_S^2 has a χ_1^2 distribution, chi-square with 1 degree of freedom.
- The P-value is the tail probability of a chi-square density with 1 *df* greater than what we saw χ_S^2. The P-value is the probability of seeing $\hat{p}_1$ and $\hat{p}_2$ *even further away from each other* than what we saw.
- We can get the P-value out of R using chisq.test, but now we need to put in a contingency table in the form of a matrix to get our P-value.

Introduction
2 × 2 contingency tables
Fishers exact test
r × k contingency table

Obtaining surgery data P-value in R

- Need to create a 2×2 matrix of values first

```
> surgery=matrix(c(41,8,15,11),nrow=2)
> colnames(surgery)=c("Real","Sham")
> rownames(surgery)=c("Success","No success")
> surgery
            Real Sham
Success       41   15
No success     8   11
```

- The default `chisq.test(surgery)` uses $\chi^2_Y = \sum_{i=1}^4 \frac{(|o_i - e_i| - 0.5)^2}{e_i}$. Called "Yates continuity correction" & gives more accurate P-values in small samples.

```
> chisq.test(surgery)

        Pearson's Chi-squared test with Yates' continuity correction

data:  surgery
X-squared = 4.7661, df = 1, p-value = 0.02902
```

Introduction
2 × 2 contingency tables
Fishers exact test
r × k contingency table

Obtaining surgery data P-value in R

- To get the usual statistic and P-value, we have to turn the Yates correction "off" using `chisq.test(surgery,correct=FALSE)`.

```
> chisq.test(surgery,correct=FALSE)

        Pearson's Chi-squared test

data:  surgery
X-squared = 6.0619, df = 1, p-value = 0.01381
```

- We reject $H_0 : p_1 = p_2$ at the 5% level. The surgery significantly reduces migraines.

- Either P-value $= 0.029$ (using Yate's) or P-value $= 0.014$ (regular) is fine.

Introduction
2 × 2 contingency tables
Fishers exact test
r × k contingency table

Two ways to collect data

- There are two ways to collect 2×2 contingency table data.
- **Cross-sectional** data is collected by randomly sampling n individuals and cross-classifying them on two variables.
- Example Ask $n = 143$ random individuals two questions: salary high/low and education high-school/college.
- The row and column totals are random.
- **Product binomial** data is collected when a fixed number from one group is sampled, and a fixed number from another group is sampled.
- Example: Real vs. sham surgery for migraine.

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

Fishers exact test

- For the chi-square test to be valid, we cannot have very small sample sizes, say less than 5 in any cell.

- For small sample sizes there is an exact test, called Fisher's exact test for testing $H_0 : p_1 = p_2$.

- Fisher's test computes all possible 2×2 tables with the same number of successes and failures (56 successes and 19 failures for the migraine study) that make $\hat{p}_1$ and $\hat{p}_2$ even further apart than what we saw, and adds up the probability of seeing each table.

- An alternative, that also works for small sample sizes, is the equivalent of the permutation test discussed at the beginning of the course, only for binary data, given by `chisq.test(surgery,simulate.p.value=TRUE)`.

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

Flu shots

A random sample of college students found that 13 of them had gotten a flu shot at the beginning of the winter and 28 had not. Of the 13 who had a flu shot, 3 got the flu during the winter. Of the 28 who did not get a flu shot, 15 got the flu.

Flu shot data				
		No shot	Flu shot	Total
Flu?	Yes	15	3	18
	No	13	10	23
	Total	28	13	41

Want to test $H_0 : p_1 = p_2$ vs. $H_0 : p_1 > p_2$ where p_1 is probability of getting flu among those without shots and p_2 is probability of getting flu among those that got shots.

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

P-value for flu shot data

Tables where p_1 and p_2 are even further apart in the direction of $H_A : p_1 > p_2$

Table		Probability
15	3	
13	10	0.05298
16	2	
12	11	0.01174
17	1	
11	12	0.00138
18	0	
10	13	0.00006

Figure 10.4.1

P-value $= 0.05298 + 0.01174 + 0.00138 + 0.00006 = 0.06616$.

Introduction
2 × 2 contingency tables
Fishers exact test
r × k contingency table

Fisher's exact test

The probability of each table is given by the *hypergeometric distribution* and is beyond the scope of this course. For the flu shot data to carry out Fisher's test we type

```
> flu=matrix(c(15,13,3,10),nrow=2)
> fisher.test(flu,alternative="greater")

        Fisher's Exact Test for Count Data

data:  flu
p-value = 0.06617
alternative hypothesis: true odds ratio is greater than 1
sample estimates:
odds ratio
  3.721944
```

We'll discuss what an odds ratio is next time. For now, we accept $H_0 : p_1 = p_2$ at the 5% level. There is <u>not</u> statistically significant evidence that getting a flu shot decreases the probability of getting the flu.

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

Directional alternatives

- Using fisher.test we can test $H_0 : p_1 = p_2$ versus one of
  (a) $H_A : p_1 \neq p_2$, (b) $H_A : p_1 < p_2$, or (c) $H_A : p_1 > p_2$.
- Use alternative="two.sided" (the default) or
  alternative="less" or alternative="greater".
- Fisher's test is better than the chi-square test; just use the
  Fisher test in your homework.
- You will use chisq.test for tables larger than 2×2 instead,
  our next topic...

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

10.5 $r \times k$ contingency table

- The number of categories is generalized to r instead of 2.
- The number of groups is generalized to k instead of 2.
- Still want to test H_0 : the probabilities of being in each of the r categories do not change across the k groups.
- In the next example, $r = 3$ categories (agricultural field, prairie dog habitat, grassland) and $k = 3$ groups (2004, 2005, 2006).

Introduction
2 × 2 contingency tables
Fishers exact test
r × k contingency table

Plover Nesting

Wildlife ecologists monitored the breeding habitats of mountain plovers for three years and made note of where the plovers nested.
Plover nest locations across three years				
	Year			
Location	2004	2005	2006	Total
Agricultural field (AF)	21	19	26	**66**
Prairie dog habitat (PD)	17	38	12	**67**
Grassland (G)	5	6	9	**20**
Total	**43**	**63**	**47**	**153**

Question: do nesting choices vary over time?

Introduction
2 × 2 contingency tables
Fishers exact test
r × k contingency table

Plover nesting percentages over time

Percentage distributions of plover nests by year			
	Year		
Location	2004	2005	2006
Agricultural field (AF)	48.8	30.2	55.3
Prairie dog habitat (PD)	39.5	60.3	25.5
Grassland (G)	11.6	9.5	19.1
Total	**99.9**[*]	**100.0**	**99.9**[*]
[*]The sums of the 2004 and 2006 percentages differ from 100% due to rounding.			

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

Stacked bar plot

If the percentages of nesting choice are the same for each year, then the gray areas will be equal.

Introduction
2 × 2 contingency tables
Fishers exact test
r × k contingency table

Chi-square test

- H_0 category percentages do not change across groups.
- The chi-square test statistic is given by

$$\chi_S^2 = \sum_{\text{all cells}} \frac{(e_i - o_i)^2}{e_i}.$$

- Here, e_i is the total number in the group (column total) times the total row percentage, i.e.

$$e = \frac{\text{row total} \times \text{column total}}{\text{grand total}}.$$

- χ_S^2 has a χ_{df}^2 where $df = (r - 1)(k - 1)$. This is where the P-value comes from.

Introduction
2 × 2 contingency tables
Fishers exact test
$r \times k$ contingency table

Plover data, observed & expected

Observed and expected frequencies of plover nests			
	Year		
Location	2004	2005	2006	Total
Agricultural field (AF)	21 (18.55)	19 (21.18)	26 (20.27)	**66**
Prairie dog habitat (PD)	17 (18.83)	38 (27.59)	12 (20.58)	**67**
Grassland (G)	5 (5.62)	6 (8.24)	9 (6.14)	**20**
Total	**43**	**63**	**47**	**153**

Upper left $18.55 = \frac{43(66)}{153}$,

$$\chi_S^2 = \frac{(21 - 18.55)^2}{18.55} + \cdots + \frac{(9 - 6.14)^2}{6.14} = 14.09.$$

Introduction
2×2 contingency tables
Fishers exact test
$r \times k$ contingency table

Chi-square test in R

```
> plover=matrix(c(21,17,5,19,38,6,26,12,9),nrow=3)
> plover
     [,1] [,2] [,3]
[1,]   21   19   26
[2,]   17   38   12
[3,]    5    6    9

> chisq.test(plover)

        Pearson's Chi-squared test

data:  plover
X-squared = 14.0894, df = 4, p-value = 0.007015
```

We reject H_0 that nesting preference does not change over time at
the 5% level.
